## Estimation of Dirichlet parameters using MoM

The function `dirichlet_params` computes the  $\alpha$  parameters of a Dirichlet distribution following the method of moments (MoM) proposed by Fielitz and Myers (1975) and Narayanan (1992).

If  $\mu$  is a vector of means and  $\sigma$  is a vector of standard deviations of the random variable, then the second moment  $X_2$  is defined by  $\sigma^2 + \mu^2$ . Using the mean and the second moment, the  $J$  alpha parameters are computed as follows

$$\alpha_i = \frac{(\mu_1 - X_{2_1})\mu_i}{X_{2_1} - \mu_1^2}$$

for  $i = 1, \dots, J - 1$ , and

$$\alpha_J = \frac{(\mu_1 - X_{2_1})(1 - \sum_{i=1}^{J-1} \mu_i)}{X_{2_1} - \mu_1^2}$$

## Estimation of Log-normal parameters using MoM

The function `lnorm_params` computes the location,  $\mu$ , and scale,  $\sigma$ , parameters of a log-normal distribution from the mean and variance of a random variable following the method of moments (MoM).

Given the non-logarithmized mean and variance  $m$  and  $v$  of the random variable, respectively, the location,  $\mu$ , and scale,  $\sigma$ , of a log-normal distribution are given by the following equations

$$\mu = \ln \left( \frac{m}{\sqrt{1 + \frac{v}{m^2}}} \right)$$

and

$$\sigma = \sqrt{\ln \left( 1 + \frac{v}{m^2} \right)}$$

## EVPPi using linear regression metamodeling

The expected value of partial perfect information (EVPPi) is the expected value of perfect information from a subset of parameters of interest,  $\theta_I$  of a cost-effectiveness analysis (CEA) of  $D$  different strategies with parameters  $\theta = \{\theta_I, \theta_C\}$ , where  $\theta_C$  is the set of complimentary parameters of the CEA. The function `evppi_lrm` computes the EVPPi of  $\theta_I$  from a matrix of net monetary benefits  $B$  of the CEA. Each column of  $B$  corresponds to the net benefit  $B_d$  of strategy  $d$ . The function `evppi_lrm` computes the EVPPi using a linear regression metamodel (Strong, Oakley, and Brennan 2014; Jalal and Alarid-Escudero 2017) approach following these steps:

1. Determine the optimal strategy  $d^*$  from the expected net benefits  $\bar{B}$

$$d^* = \arg \max_d \{\bar{B}\}$$

2. Compute the opportunity loss for each  $d$  strategy,  $L_d$

$$L_d = B_d - B_{d^*}$$

3. Estimate a linear metamodel for the opportunity loss of each  $d$  strategy,  $L_d$ , by regressing them on the spline basis functions of  $\theta_I$ ,  $f(\theta_I)$

$$L_d = \beta_0 + f(\theta_I) + \epsilon,$$

where  $\epsilon$  is the residual term that captures the complementary parameters  $\theta_C$  and the difference between the original simulation model and the metamodel.

4. Compute the EVPPI of  $\theta_I$  using the estimated losses for each  $d$  strategy,  $\hat{L}_d$  from the linear regression metamodel and applying the following equation:

$$\text{EVPPI}_{\theta_I} = \frac{1}{K} \sum_{i=1}^K \max_d (\hat{L}_d)$$

The spline model in step 3 is fitted using the `mgcv` package.

## Cost-effectiveness acceptability curves (CEAC) and Frontier (CEAF)

The cost-effectiveness acceptability curves (CEAC) determine the probability of each strategy being cost effective by willingness-to-pay (WTP) threshold (Van Hout et al. 1994). The cost-effectiveness acceptability frontier (CEAF) determines the optimal strategy –defined as the strategy with the highest net benefit– by WTP (Fenwick, Claxton, and Sculpher 2001). The function `ceaf` computes both the CEAC and CEAF and returns a data frame and a `ggplot2` objects of these outcomes.

To run the `ceaf` function you need a PSA, specify the strategies, the cost and effectiveness of these, and different values of WTP thresholds. The following code produces the CEAC and CEAF of the breast cancer CEA example included in this package.

```
# Load PSA dataset
data(psa)
# Name of strategies
strategies <- c("Chemo", "Radio", "Surgery")
# Vector of WTP thresholds
v.wtp <- seq(1000, 150000, by = 10000)
# Matrix of costs
m.c <- psa[, c(2, 4, 6)]
# Matrix of effectiveness
m.e <- psa[, c(3, 5, 7)]

out <- ceaf(v.wtp = v.wtp, strategies = strategies, m.e = m.e , m.c = m.c)
gg.ceaf <- out$gg.ceaf
plot(gg.ceaf)
```

## Vignette Info

Note the various macros within the `vignette` section of the metadata block above. These are required in order to instruct R how to build the vignette. Note that you should change the `title` field and the `\VignetteIndexEntry` to match the title of your vignette.

## Styles

The `html_vignette` template includes a basic CSS theme. To override this theme you can specify your own CSS in the document metadata as follows:

Figure 1: Cost-effectiveness acceptability curves (CEAC) and forntier (CEAF).

output:  
 rmarkdown::html\_vignette:  
 css: mystyles.css

## More Examples

You can write math expressions, e.g.  $Y = X\beta + \epsilon$ , footnotes<sup>1</sup>, and tables, e.g. using `knitr::kable()`.
